March 2007

Are you risking the protection of your MySQL data with complex scripting or by not including MySQL in your data protection strategy?

NetVault: Backup Application Plugin Module (APM) for MySQL is a MySQL Enterprise Gold Certified Solution and the first enterprise-class data protection solution for mission-critical applications that consolidates the backup and recovery of multiple MySQL storage engines into a single job without complex scripting. In addition to performing full, incremental, or differential backups while data is online and accessible, point-in-click restores with both time-based and position-based point-in-time options allowing the DBA to restore only what is required therefore significantly reducing data loss.

While increasing confidence and reducing risk when deploying MySQL, NetVault: Backup APM for MySQL also speeds up restores to reduce downtime and ensures business continuity with automatic integration with backup devices.

NetVault: Backup APM for MySQL v3.0 is now generally available and includes the following enhancements:

- Support for MySQL 5.0.x and FreeBSD
- Support for native MySQL Replication
- Differential backups
- Additional support for storage engines such as Federated, Berkley (BDB), Archive, and CSV
